BLR compression – Symbolic factorization

Full-rank matrix.

Block Low-Rank matrix.
MM vs JIT: DAG of tasks

**Minimal Memory**
- Compress all off-diagonal blocks before starting the factorization
- Update low-rank blocks

**Just-In-Time**
- Compress each block when fully updated
- Update full-rank blocks
MM vs JIT: updates with two contributions

Low-rank updates (*Minimal Memory*):

\[ C_1 = \text{Low-rank update} \left( C_{\text{early}} = C_0, \text{contrib}_1 \right) \]

\[ C_{\text{final}} = C_2 = \text{Low-rank update} \left( C_1, \text{contrib}_2 \right) \]

Full-rank updates (*Just-In-Time*):

\[ C_1 = \text{Dense update} \left( C_{\text{init}} = C_0, \text{contrib}_1 \right) \]

\[ C_{\text{final}} = \text{Compression} \left( \begin{bmatrix} C_2 \\ C_1 \end{bmatrix} = \text{Dense update} \left( C_1, \text{contrib}_2 \right) \right) \]

Both strategies have the same contributions as inputs and the same final low-rank matrix as output
Limitations

**Minimal Memory**
- Never use the blocks in their full-rank form: consumes as little memory as possible
- Expensive low-rank updates to maintain low-rank structures

**Just-In-Time**
- Efficient updates
- Compress blocks during the factorization: more memory consuming

The objective is to propose a **memory-aware** strategy that uses as much memory as possible to speedup updates while remaining under a memory constraint.
Outline

1. Context
2. A new strategy
3. Experiments
Each block can be considered independently

**Idea: two possible modes**

- *early* mode (as in the *Minimal Memory* strategy): execution time $T_i$ (sum of the updates) and memory $s_i = r_i \times (m_i + n_i)$.
- *lazy* mode (as in the *Just-In-Time* strategy): execution time $t_i$ (sum of the updates) and memory $S_i = m_i \times n_i$;
- Execute a set of blocks in *early* mode to respect the memory **constraint**
- Execute other blocks in *lazy* mode to perform **efficient operations**
A new strategy

Experiments

General approach

Algorithm

- For a given memory constraint $M$, choose the sets for being as fast as possible
- This algorithm is equivalent to Knapsack: we inherit its NP-hardness and all approximation algorithms with the same approximation factor
- Sort blocks in a greedy approach (2-approximation) accordingly to $\frac{T_i - t_i}{S_i - s_i}$

Assumptions

- $i \in [1 : n], S_i > s_i$ and $T_i > t_i$
- Otherwise, if $S_i \leq s_i$ it is always better to execute the task in lazy mode and if $T_i \leq t_i$ it is always better to use the early mode.
Equivalence with Knapsack (1/2)

Knapsack problem

Let $I$ be a set of $n$ items. Each item has a value $v_i$ and a weight $w_i$. The objective is to fit some of the items in a bag of weight capacity $W$, while maximizing the value of the objects inside the bag.

We associate a variable $x_i \in \{0, 1\}$ to each $J_i \in [1 : n]$. Let

- $x_i = 1$ if the task $J_i$ is executed in lazy mode,
- $x_i = 0$ if the task $J_i$ is executed in early mode.

Therefore, the ILP formulation is:

\[
\begin{align*}
\text{minimize} & \quad \sum_{i=1}^{n} (x_i t_i) + \sum_{i=1}^{n} ((1 - x_i) T_i) \\
\text{subject to} & \quad \sum_{i=1}^{n} (x_i S_i) + \sum_{i=1}^{n} ((1 - x_i) s_i) \leq M \\
\text{and} & \quad \forall i \in \{1, n\}, \ x_i \in \{0, 1\}
\end{align*}
\]
Equivalence with Knapsack (2/2)

We have the following relations:

(1) \iff \max \sum_{i=1}^{n} x_i (T_i - t_i) - \sum_{i=1}^{n} T_i \iff \max \sum_{i=1}^{n} x_i (T_i - t_i)

(2) \iff \sum_{i=1}^{n} x_i (S_i - s_i) \leq M - \sum_{i=1}^{n} s_i

Thanks to these two equivalences, we just showed that it is exactly a linear formulation of the Knapsack problem:

\[
\max \sum_{i=1}^{n} x_i v_i \quad \text{subject to} \quad \sum_{i=1}^{n} x_i w_i \leq W \quad \text{and} \quad \forall i \in \{1, n\}, x_i \in \{0, 1\}
\]

with the following transformation:

- \forall i \in [1 : n], v_i = T_i - t_i \quad \text{and} \quad \forall i \in [1 : n], w_i = S_i - s_i
- \quad W = M - \sum_{i=1}^{n} s_i

Therefore, our problem is NP-complete
Approximation quality – theory

Algorithm 1 Greedy approximation algorithm

1. Sort tasks by non-increasing \( \frac{T_i - t_i}{S_i - s_i} \) values
2. Greedily add tasks to a set \( S \) while the sum of their weights \( w_i = S_i - s_i \) does not exceed \( M - \sum_{i=1}^{n} s_i \)

Our algorithm is a \((1 + 2\varepsilon \rho)\)-approximation of our problem

- \( \varepsilon = \max_i \frac{S_i}{(M - \sum_j s_j)} \) (ratio size largest blocks wrt remaining memory)
- \( \rho = \frac{\sum_i T_i}{\sum_i t_i} \) (overhead of MM wrt JIT)
Approximation quality – in practice

(1 + 2ερ)-approximation of our problem

- $\varepsilon = \max_i S_i / (\mathcal{M} - \sum_j s_j)$
- $\rho = (\sum_i T_i) / (\sum_i t_i)$

Practical values leading to a 1.02-approximation

- $\rho \leq 10$, it corresponds to the ratio between the execution times of the Minimal Memory and Just-In-Time strategies
- $\varepsilon \leq 0.001$
  1. Block size is lower than 256 (splitting) thus $\max_i S_i \approx 0.5$ MB
  2. Let us assume that $\mathcal{M} \geq 1.1 \times \sum_j s_j$ and that the overall memory is larger than 5GB
  3. $\mathcal{M} - \sum_j s_j \geq 0.1 \sum_j s_j \geq 0.5$ GB
The mode of each block has to be chosen before starting the factorization. Unfortunately, the time and the memory consumption depend on the rank of the matrix. The rank depends on numerical properties and cannot be known before the factorization.

**Issue**
- The mode of each block has to be chosen before starting the factorization
- Time and memory for each mode depend on the rank
- The rank depends on numerical properties: cannot be known in advance
Models to estimate $T_i$, $t_i$ and $s_i$ (1/2)

### Memory consumption model

- We made a linear regression for the rank ($s_i = r_i \times (m_i + n_i)$), depending on
  1. the initial rank
  2. the height $m_i$
  3. the width $n_i$
  4. the surface $m_i n_i$
  5. the number of updates the block receives.

### Time model: sum of update’s time

- We made a linear regression with the different parameters, knowing the theoretical complexity of an update
- When a rank appears, we use the five parameters given above instead
Results: actual vs predicted orders of blocks

Three categories

- Blocks that are always better in *early* mode ($T_i \leq t_i$)
- Blocks to treat with Knapsack, sorted by $\frac{T_i - t_i}{S_i - s_i}$
- Blocks that are always better in *lazy* mode ($S_i \leq s_i$)

Conclusions

- Training with one matrix and testing with another
- General trend
- Imprecise
Outline

1. Context
2. A new strategy
3. Experiments
A new strategy

Experimental context

Solver / machine
- PaStiX, used in sequential
- Intel Xeon E5-4620, using MKL 2018

Matrices
- Geo1438: geomechanical model of earth (1 437 960 non-zeroes)
- Hook1498: model of a steel hook (1 498 023 non-zeroes)
- Serena: gas reservoir simulation (1 391 349 non-zeroes)
Full algorithm for the *memory-aware* strategy

1. Run the factorization using *Just-In-Time* and *Minimal Memory* strategies for the training matrix and **train** the time and the memory models.

2. Use the models for the **test** matrix.

3. **Select** blocks that should always be treated in **lazy mode** \(s_i \geq S_i\) as well as blocks that should always be treated in **early mode** \(t_i \geq T_i\);

4. **Sort** the remaining blocks by decreasing value of \(\frac{T_i - t_i}{S_i - s_i}\);

5. Choose a sufficient number of blocks (following the order) to perform in **early mode** in order to **respect the memory constraint** and keep remaining blocks in **lazy mode** in order to **perform efficient updates**

6. If the memory increases during the factorization and would exceed the memory limit, we compress the next block in the previous order (we switch this block to **early mode**). This is required for actual runs of the solver as we cannot know the exact evolution of the memory consumption of low-rank blocks before the actual factorization.
Simulation, train=Serena, test=Geo1438, \( tol = 10^{-8} \)

Ratios depicted

- Decreasing theoretical ratio \( \frac{T_i - t_i}{S_i - s_i} \)
- Decreasing predicted ratio \( \frac{T_i^* - t_i^*}{S_i - s_i^*} \)
- Decreasing number of updates (count) received by a block
- Random order, for baseline comparison.

Conclusions

- Excellent trade-off between time and memory, much better than a naive approach
- Close to the best solution, knowing perfectly all information
## Results on real execution (train with Serena, $tol = 10^{-8}$)

### Implementation
- Blocks are first sorted
- Dynamic memory controller
- Memory can increase due to rank growth
- Memory can decrease when blocks are compressed
Conclusion

A memory-aware strategy
- Proof of concept for the sequential case
- Implemented into the PaStiX solver
- Allow to reach the best of both worlds?
- Interesting trade-offs: with 30% extra memory, divide time by 3

Open research
- Parallel experiments with a parallel memory controller
- Consider the critical path to better choose the mode of each block
